

# Aquifer analogue study to determine the effects of fracture networks regarding the deposition of CO<sub>2</sub>

Axel Weitkamp, Georg Houben & Thomas Himmelsbach

GEOFRANKFURT 2014  
Goethe Universität Frankfurt a. M.

# Task 4.1: Evidence for the impact of faults and fractures on CO<sub>2</sub> migration from natural analogue studies

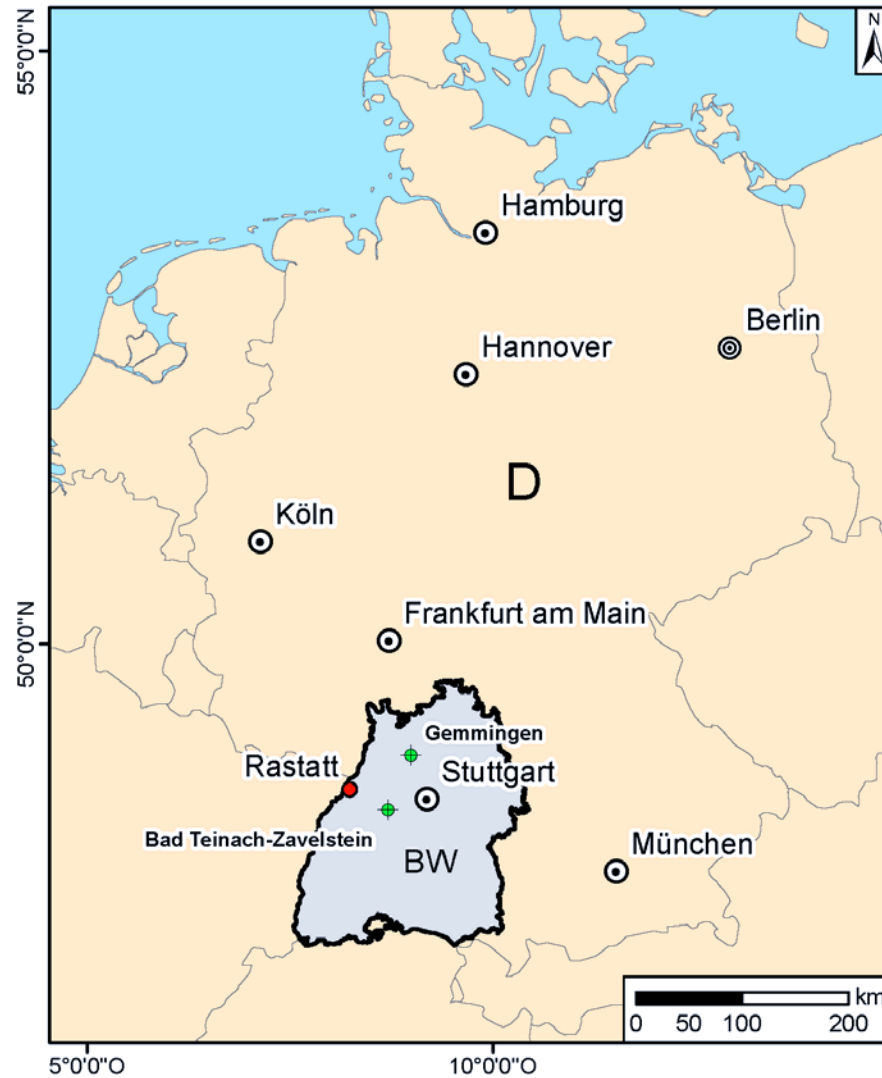

source BRGM

# Natural Analogue Studies

---

- **Idea:** Study effects of ascending CO<sub>2</sub> (and trace gases) on the mineralogical and geochemical rock composition in the near-field of fractured outcrop walls
- **Step I: Analysis of core material**  
Samples taken from two research drillings in Baden-Württemberg from Triassic Vogesensandstein-Fm. (sV) to Permian Tigersandstein-Fm. (zT)
- **Step II: Field measurements**  
Geo-statistical data analysis of fracture patterns and the physical properties of rock material

# Natural Analogue Sites in Baden-Württemberg

# Geological Setting

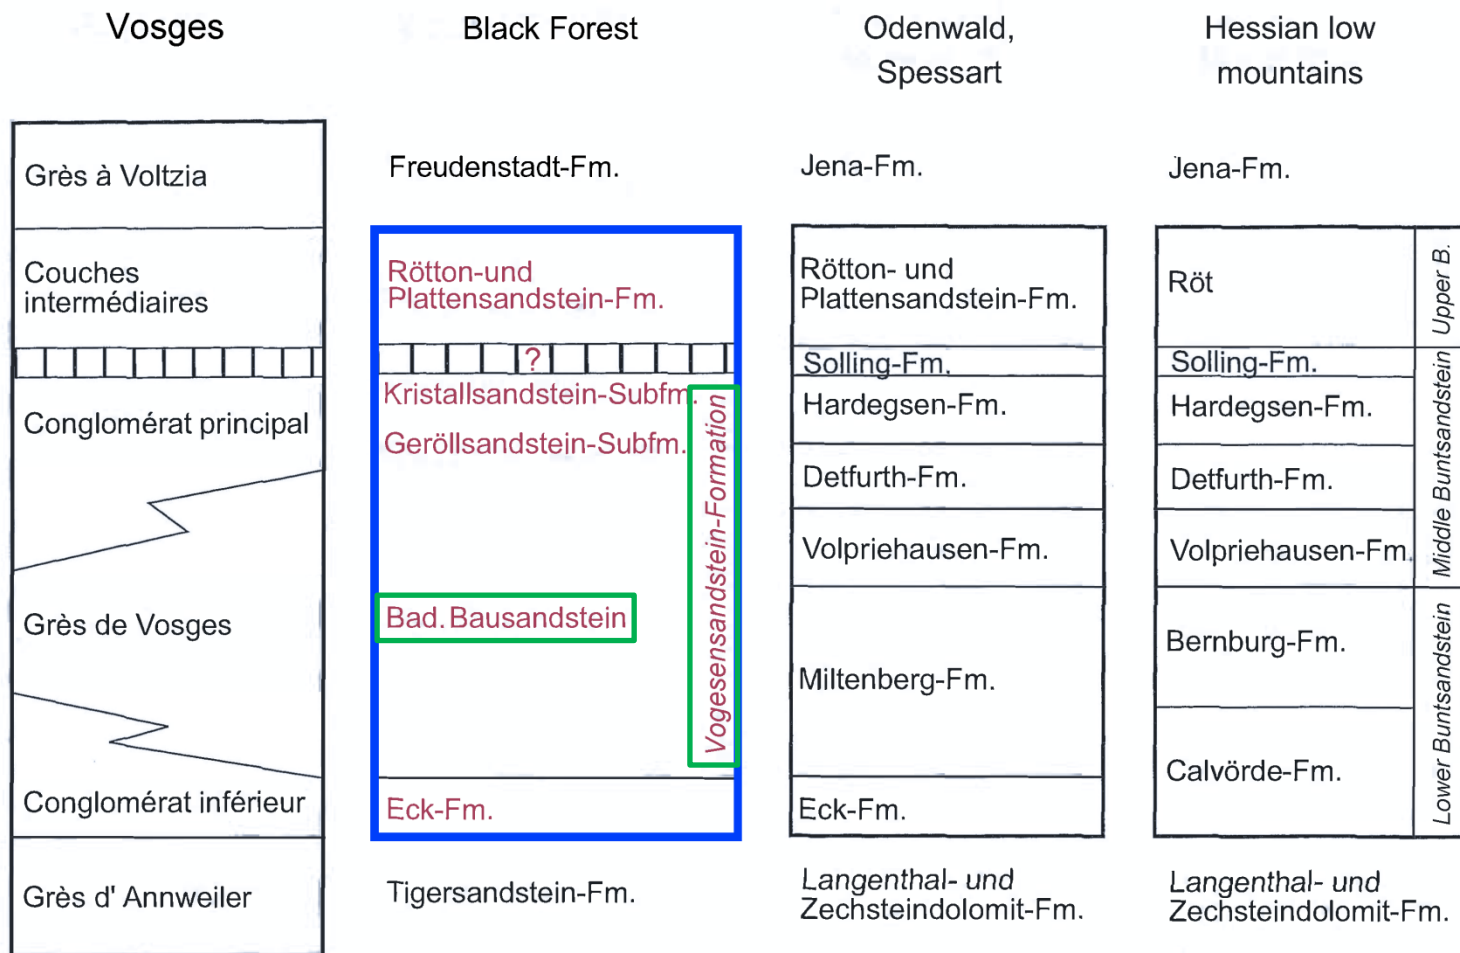

## Legend

- |                        |                          |
|------------------------|--------------------------|
| Quaternary             | Keuper (Triassic)        |
| Paleogene, Neogene     | Muschalkalk (Triassic)   |
| younger magmatic rocks | Buntsandstein (Triassic) |
| Upper Jurassic         | Zechstein (Permian)      |
| Middle Jurassic        | Rotliegend (Permian)     |
| Lower Jurassic         | bedrock                  |

(modified after RUPF & NITSCH 2008)

# Geological Setting

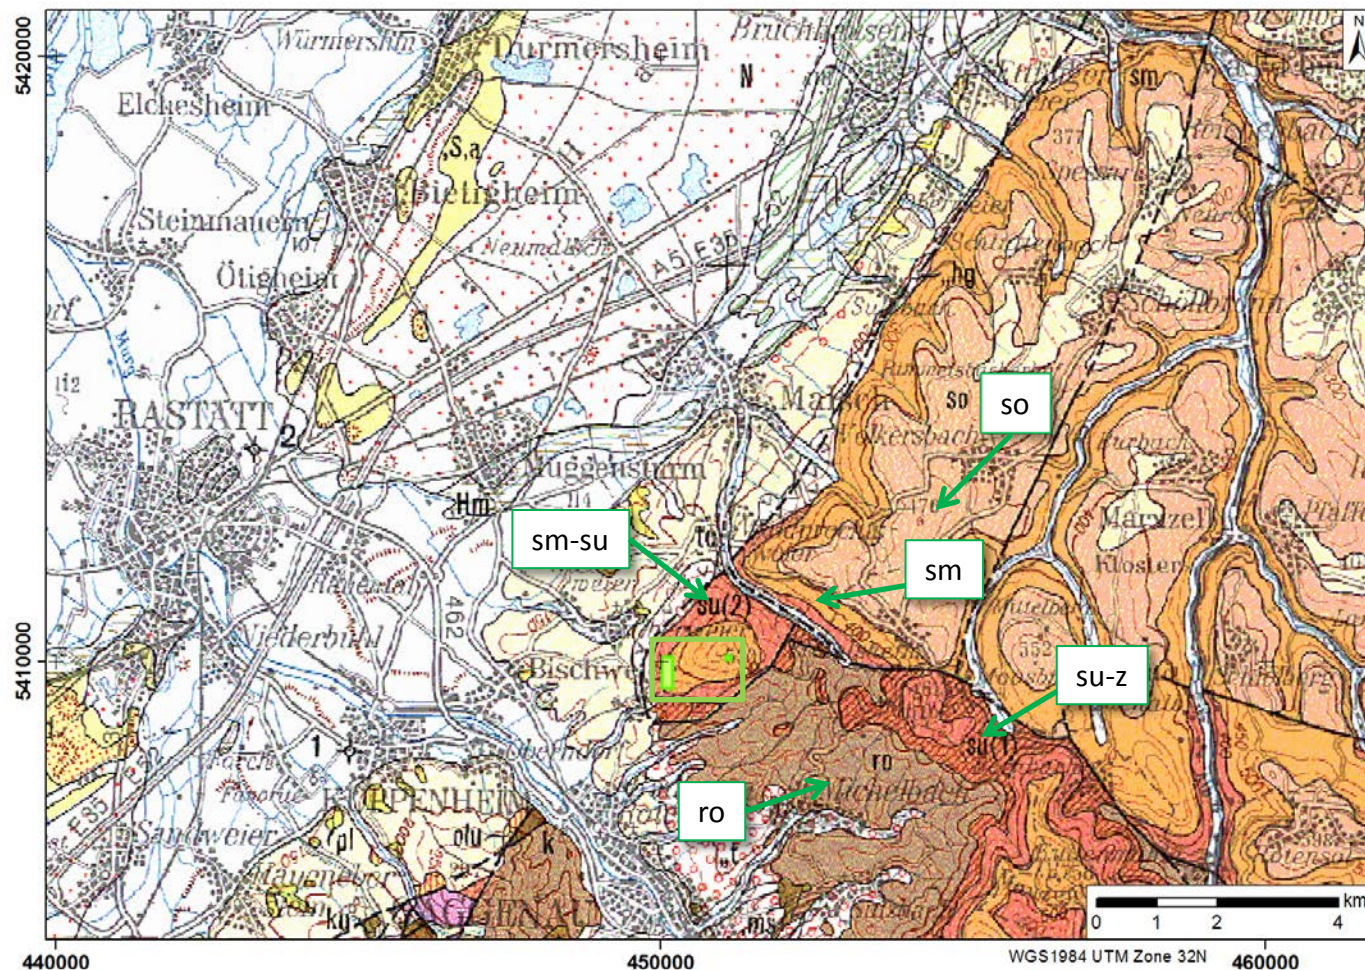

- Correlation of Buntsandstein formations from France and Germany

(modified after GEYER & GWINNER 2011)

# Geological Setting

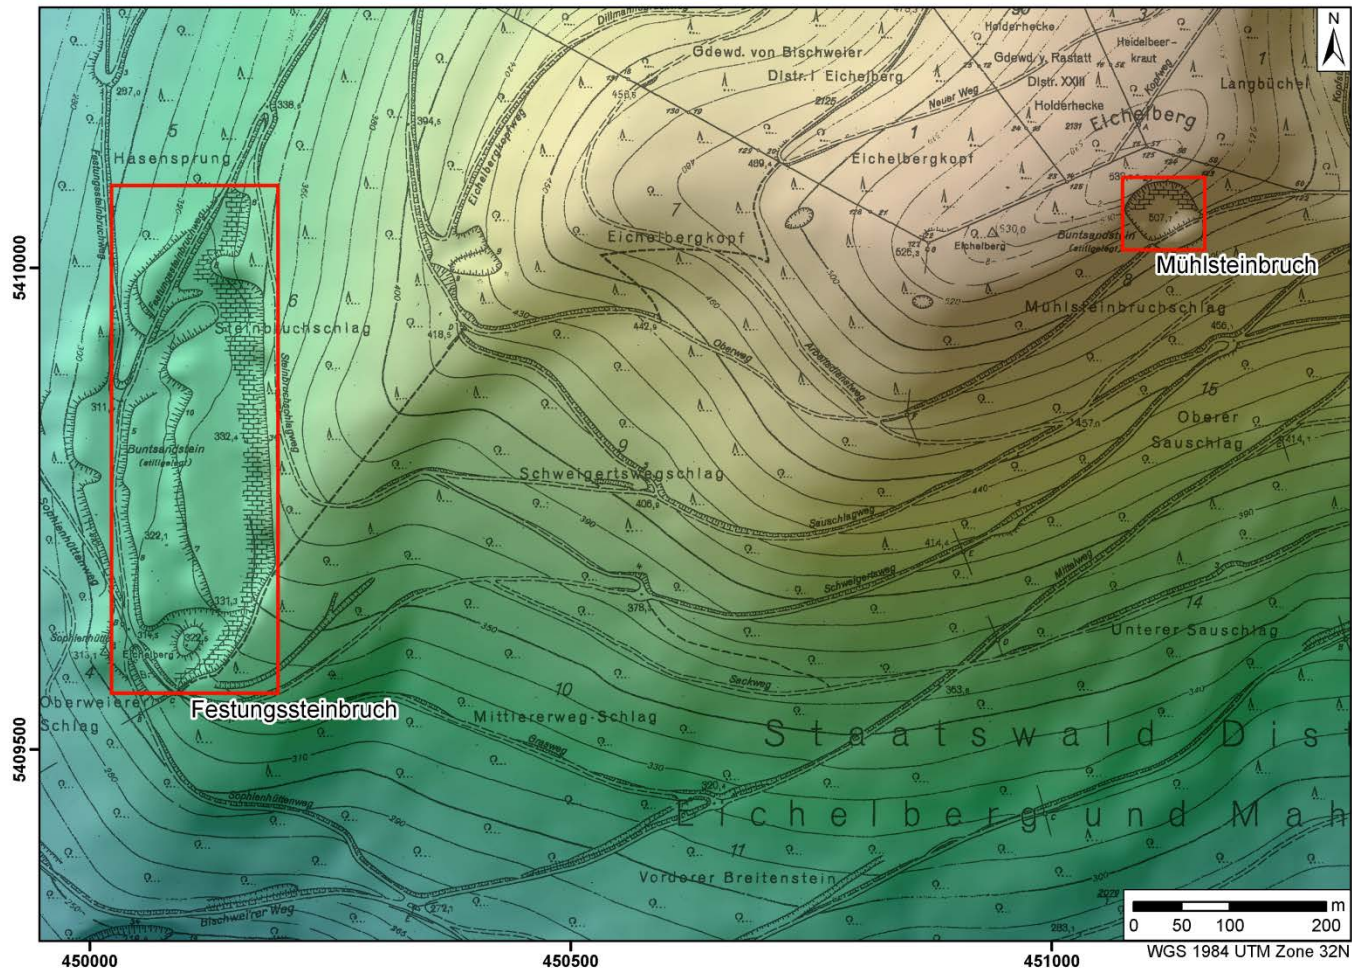

- Geological map (GÜK200) of the northern Black Forest with study area

(modified after BGR 1986)

# Outcrop sites

- Topographical map (DTK5) of the Eichelberg with DEM10 data

(source BKG, LGL)

# Outcrop sites

- Festungssteinbruch (massive sandstone layering, intercalated mudstone)

# Data collection I

---

- Terrestrial Laser Scanning system in field operation

# Data collection I

- Section from calculated 3D surface model (point cloud: density depending on distance to the scanned object, acquiring 2500 points/s)

# Data collection II

scanline technique

(HIMMELSBACH 2007)

- Raw data are collected as dip direction (azimuth) and dip angle (also for the fixed tape measure) with a geological compass
- Transformation in normal vector data for further evaluation

# Data collection II

(HIMMELSBACH 2007)

- Scanline procedure is objective
- All the dividing planes along the profile are measured
- Oversampling occurring while measuring parallel lines is intended
- But it incorporates systematic error sources
- Error can be minimized by arranging the scanlines in different spacial directions almost perpendicular to one another

# Statistics

(HIMMELSBACH 2007)

- Geometrical error of the „blind zone“
- Fractures that are oriented approximately parallel to the outcrop wall are statistically underrepresented
- The amount of recorded fractures along a scanline is dependent on its orientation to the dividing planes

# Statistics (vectorial data)

- Before weighting
- After weighting
- Cluster centers characterized by Fisher distributions with a critical angle of selection can be defined
- Calculation of spherical degree of opening  $\omega$  and k-factor as input data for GOCAD modelling

# Statistics (scalar data)

- Frequency distribution of fracture lengths
- Chosen class width 0,5 m

# Statistics (scalar data)

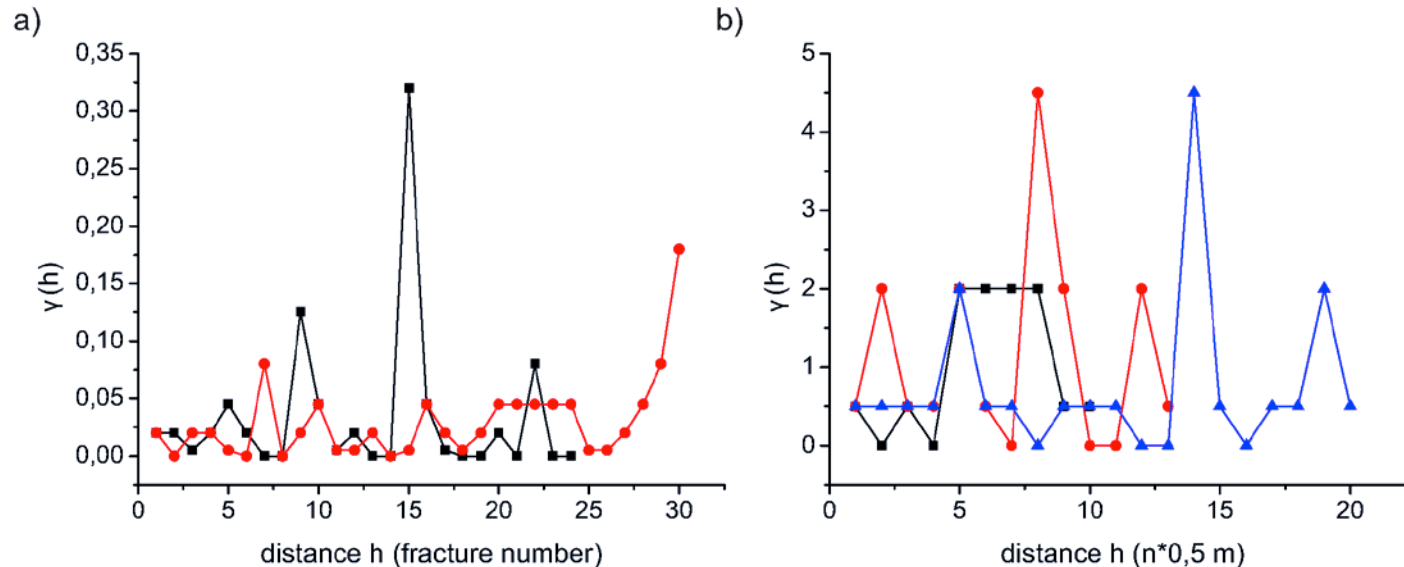

- Empirical fracture length distribution (all data, black line)
- Functions for Erlang-2 (green curve, best fit for scanline measurements) and expected exponential distribution for the whole outcrop (dashed blue curve)
- Length overestimation by scanline measurements visible

# Statistics (scalar data)

- Fracture distance distribution for a single scanline (black line)
- As spacial random distribution a negative exponential distribution can be closely adapted ( $a=3,4$ /dashed blue curve)

# Statistics (scalar data)

- Variograms of fracture distance (a) and density (b) show no spatial correlation for the examined areas
- But in outcrop scale a spatial correlation cannot be ruled out completely

# Statistics (fracture abundance)

		Dimension of Feature				
		0	1	2	3	
Dimension of Sampling Region	0	<b><math>P_{00}</math> Length<sup>0</sup></b> Number of Fracture Samples per Point Sample of Rock Mass				← POINT MEASURES
	1	<b><math>P_{10}</math> Length<sup>-1</sup></b> Number of Fractures per Unit Length of Scanline ( <i>Frequency or Linear Intensity</i> )	<b><math>P_{11}</math> Length<sup>0</sup></b> Length of Fracture Intersects per Unit Length of Scanline ( <i>Linear Porosity</i> )			← LINEAR MEASURES
	2	<b><math>P_{20}</math> Length<sup>-2</sup></b> Number of Trace Centers per Unit Sampling Area ( <i>Areal or Trace Density</i> )	<b><math>P_{21}</math> Length<sup>-1</sup></b> Length of Fracture Traces per Unit Sampling Area ( <i>Areal or Trace Intensity</i> )	<b><math>P_{22}</math> Length<sup>0</sup></b> Area of Fractures per Unit Sampling Area ( <i>Areal Porosity</i> )		← AREAL MEASURES
	3	<b><math>P_{30}</math> Length<sup>-3</sup></b> Number of Fracture Centers per Unit Rock Volume ( <i>Volumetric Density</i> )	<b><math>P_{31}</math> Length<sup>-1</sup></b> Length of Fracture Traces per Unit Rock Volume ( <i>Volumetric Intensity</i> )	<b><math>P_{32}</math> Length<sup>-1</sup></b> Area of Fractures per Unit Volume of Rock Mass ( <i>Volumetric Intensity</i> )	<b><math>P_{33}</math> Length<sup>0</sup></b> Volume of Fractures per Unit Volume of Rock Mass ( <i>Fracture Porosity</i> )	← VOLUMETRIC MEASURES

↑ DENSITY      ↘ INTENSITY      ↘ POROSITY

- Intensity  $P_{10}$  can easily be derived from scanline measurements
- Intensity  $P_{32}$  can be calculated from  $P_{10}$  and conversion factor (input data for FracMV™)

(DERSHOWITZ & HERDA 2012)

# Modelling (input data GOCAD)

---

- SGrid object (3D grid which can be cut and deformed to fit a structural surface model)
- Fracture intensity ( $P_{32}$ : fracture area per cubic meter)
- Fracture length (minimum/maximum, power law distribution, exponent)
- Fracture orientation (dip direction, dip angle, Fisher distribution with k-parameter representing fracture concentration)
- Fracture aspect ratio (height:length, default 1:2, horizontal layering)
- Fracture aperture (proportional to length, proportional to square root of length or constant)

# Modelling (results and evaluation)

- Cluster 2 (red) and 4 (green) similar strike direction but different dip direction

# Modelling (results and evaluation)

- Cluster 1 (yellow) and 5 (blue) similar strike direction but different dip direction

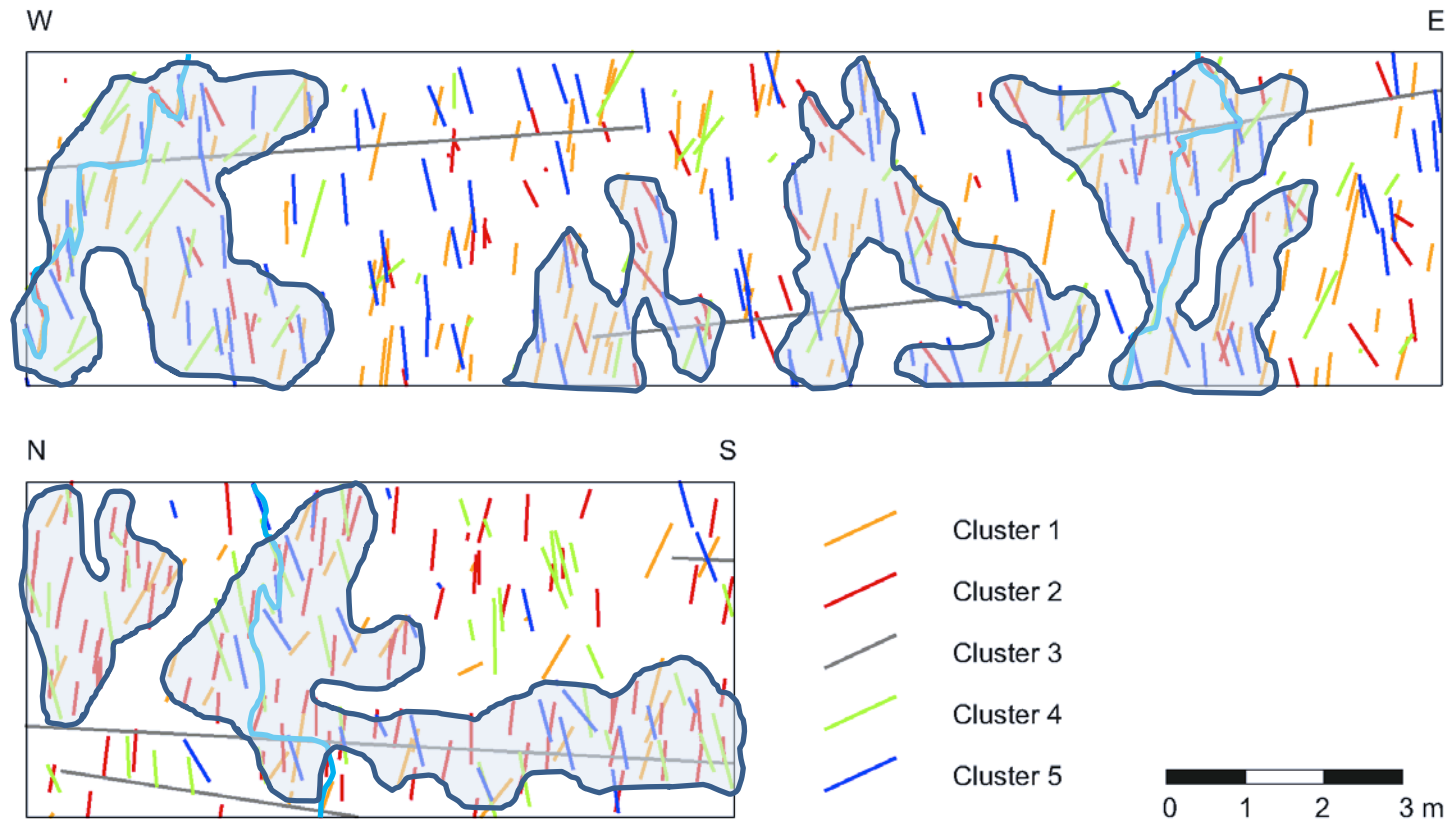

# Modelling (results and evaluation)

---

- Cluster 3 representing subhorizontal bedding planes

# Modelling (results and evaluation)

- Cross sections in mutually perpendicular directions
- Possible percolation paths for an assumed vertical hydraulic gradient
- Areas of high fracture connectivity (Percolation threshold reached?)

# Summary and Outlook

---

- For the stochastic creation of a 3D fracture model as basis for numerical flow and transport calculations it is necessary to collect as many data as possible of the rock complex of interest.
- Therefore a combination of methods like TLS and compass measurements is a good option.
- Measurements of fracture orientation, length and offset supply relative exact results.
- The raw data have to be evaluated and corrected statistically in order to reveal the genuine distributional patterns.
- If possible, anisotropy as a possible source of error should be ruled out.

# Summary and Outlook

---

- Averaging and restriction to cluster centres cause loss of information
- Decisive for the migration of fluids along fractures is if the fracture density is sufficient to create a linked fracture network which reaches the so called percolation threshold.
- The 3D model shall be utilized to characterize the transport properties of fractured rocks by determining values for porosity and permeability.
- Detailed information about distribution patterns of fracture filling, roughness and aperture are task of further investigations and therefore could only be first approximations.

# Summary and Outlook

## Permeability of fractured rock aquifers

Derived from Hagen-Poiseuille “Cubic Law”

$$K = N \cdot \frac{\rho \cdot g}{\eta} \cdot \frac{b^3}{12 \cdot f}$$

cubic !!!

- $N$  = number of parallel fractures
- $b$  = width of fracture (aperture)
- $f$  = surface roughness of fractures
- $\rho$  = density of water
- $\eta$  = kinematic viscosity of water
- $g$  = gravity constant

(source: SNOW 1969)

# Summary and Outlook

XRD/XRR

thin sections

surface scans

SEM/EDX

aperture
